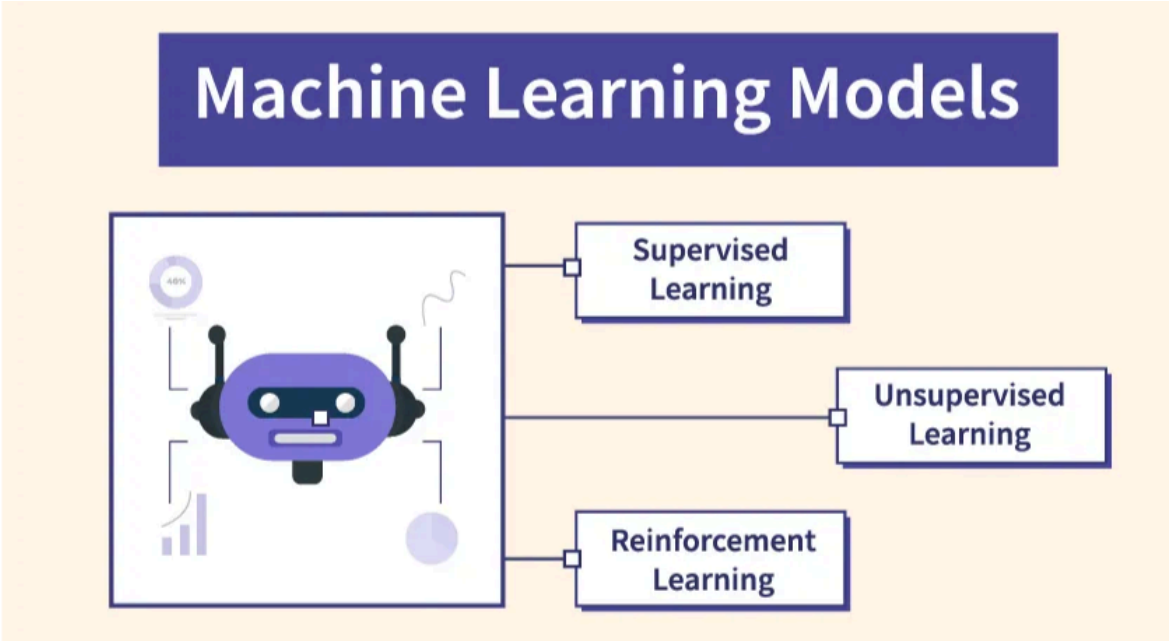
Machine Learning model

a ml model tries to find relation btw features and label

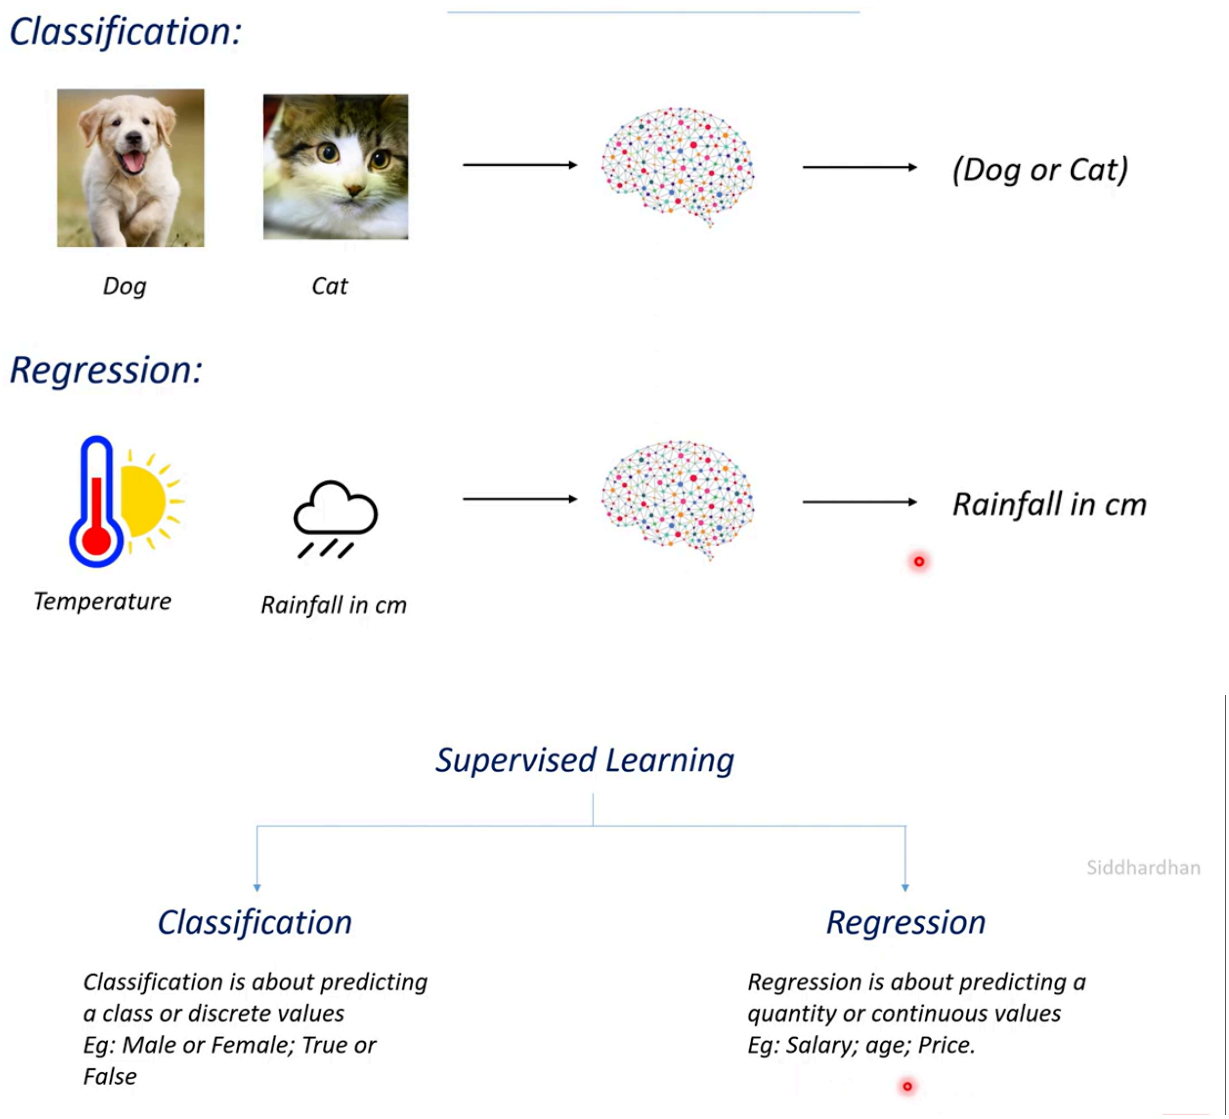
based on types of outputs (target) we classify them as below



1.Suppervised learning and there models

in this the model is feeded with a labeled data LIKE it has an idea about the type of output

depending on type of labeled output they are below types



models in suppervised learning

Supervised Learning Models

Classification:

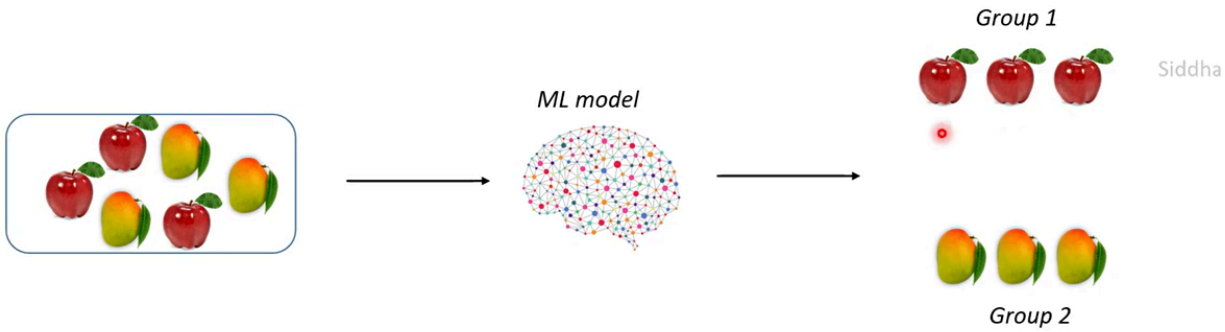
1. Logistic Regression
2. Support Vector Machine Classifier
3. Decision Tree
4. K-Nearest Neighbors
5. Random Forest
6. Naïve Bayes Classifier

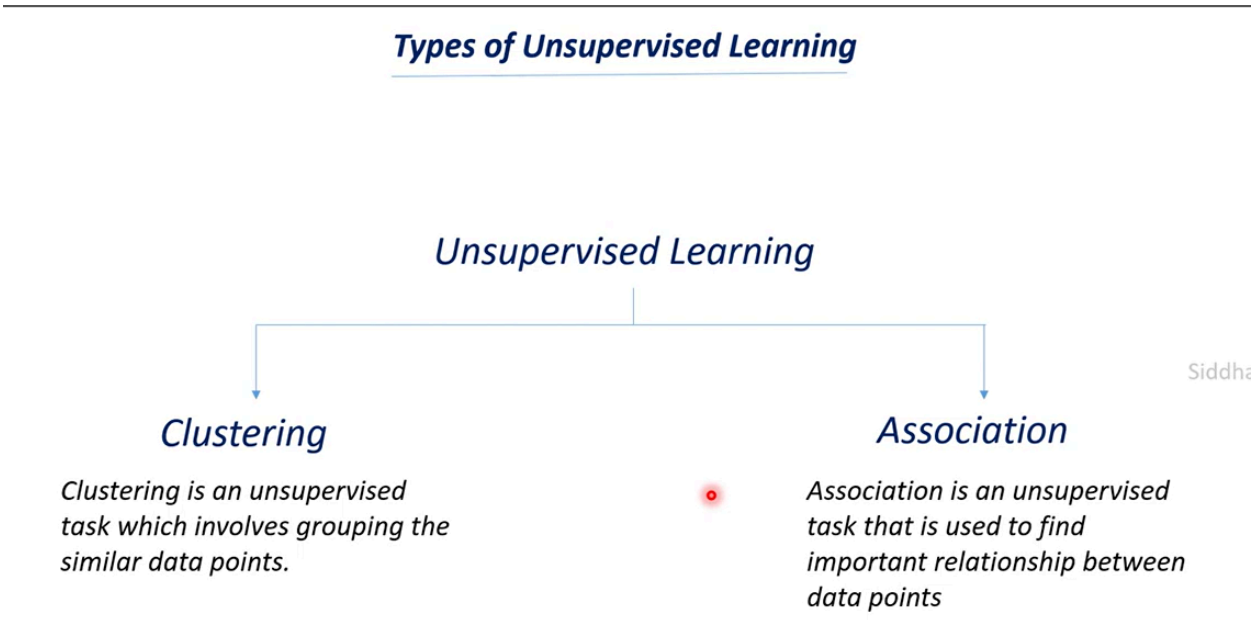
Regression:

1. Linear Regression
2. Lasso Regression
3. Polynomial Regression
4. Support Vector Machine Regressor
5. Random Forest Regressor
6. Bayesian Linear Regressor

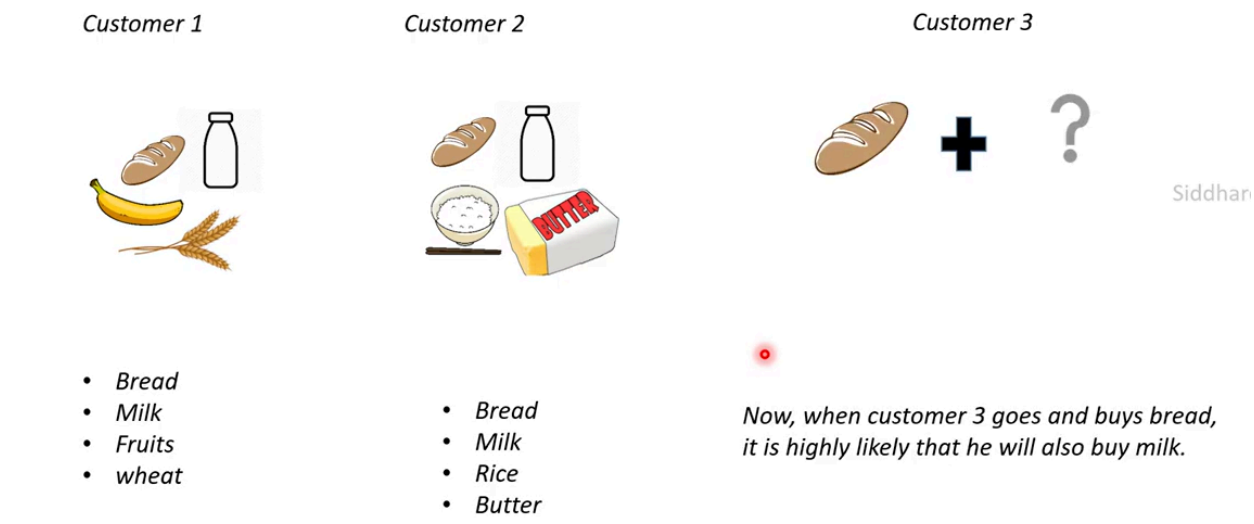
2.Unsuppervised learning and there models

we feed the model without any labelled data like it is not aware of type of output so it tries to segregate them





Association example:



used in recommandation systems

Unsupervised Learning Models

1. K-Means Clustering
2. Hierarchical Clustering
3. Principal Component Analysis (PCA)
4. Apriori
5. Eclat

Reinfored learning

it is used to when we need a desired outputs

ex: stockmarket selection to invest
